Andoung Snay is located in the district of Rolea B'ier. The population of this commune is approximately 5097 (2004). Groundwater sample collection occurred in September 2009 and consisted of the sampling of 14 tube wells throughout the commune. The attached figure presents the location of Andoung Snay within Kampong Chnang as well as groundwater sample locations and exceedances of health-impacting contaminants (when applicable).

**Groundwater Quality Rating**

The groundwater quality rating for Andoung Snay is 27F. Therefore, the general safety of deep aquifer groundwater is extremely poor and the aesthetic quality of the water is poor, according to the contaminants measured and samples collected. The following two sections describe all major health and aesthetic contaminants that exceeded drinking water standards in at least one sample within the commune.

**Contaminants of Potential Concern – Health**

Manganese - Elevated concentrations of Manganese were observed within the commune. The estimated probability of encountering unacceptable concentrations of Manganese (>0.4 mg/L) in tube wells is 75%, based on the observed data. Exposure to elevated concentrations of Manganese can cause neurological disorders. Aeration allows oxygen to enter the water and react with Manganese to form a compound which is insoluble in water. The newly formed solids will slowly settle to the bottom or can be removed more rapidly by filtration. Performing these procedures may reduce the concentration of Manganese in water but follow-up testing is recommended to ensure water quality standards are met.

**Contaminants of Potential Concern – Aesthetic**

Iron - Elevated concentrations of Iron were observed within the commune. The estimated probability of encountering potentially unacceptable concentrations of Iron (>1 mg/L) in tube wells is 24%, based on the observed data. At elevated concentrations, Iron causes water to be cloudy and unpleasant to drink. An odor may also be encountered at high concentrations. Iron can also stain laundry, food (can cause discoloration of cooked rice), and leave deposits. Aeration allows oxygen to enter the water and react with Iron to form...
a compound which is insoluble in water. The newly formed solids will slowly settle to 
the bottom or can be removed more rapidly by filtration. Performing these procedures 
may reduce the concentration of Iron in water but follow-up testing is recommended to 
ensure water quality standards are met.

Manganese - Elevated concentrations of Manganese were observed within the commune. 
The estimated probability of encountering unacceptable concentrations of Manganese 
(>0.4 mg/L) in tube wells is approximately 75%, based on the observed data. At elevated 
concentrations, Manganese causes water to be cloudy and unpleasant to drink. 
Manganese can also stain laundry, food (can cause discoloration of cooked rice), and 
leave deposits. Aeration allows oxygen to enter the water and react with Manganese to 
form a compound which is insoluble in water. The newly formed solids will slowly settle 
to the bottom or can be removed more rapidly by filtration. Performing these procedures 
may reduce the concentration of Manganese in water but follow-up testing is 
recommended to ensure water quality standards are met.

Turbidity - Elevated levels of Turbidity were observed within the commune. The 
estimated probability of encountering potentially unacceptable levels of Turbidity (>20 
ntu) in tube wells is 13%, based on the observed data. Turbid or cloudy water appears 
unpleasant to the eye and is more likely have an unpleasant taste or odor. Turbidity can 
be reduced by filtration.
Tube Well Sample Locations and Health-Based Exceedances
